

Foundation Testing Just Got a Lot Smarter

Pile Dynamics, Inc., an ADSC Associate Member, supplies the foundation industry with a vast line of quality assurance and testing systems. Dynamic Pile Testing has been around for more than thirty years and is known as an economical and fast alternative to static load testing of deep foundations. The dynamic test consists of installing gages on a foundation and connecting them to a Pile Driving Analyzer (PDA). The gages acquire the necessary measurements while the pile is being driven (or while a non-driven pile is impacted by an adequate drop weight). Test results include an estimate of the capacity of the foundation, integrity evaluation and, for driven piles, driving stresses and hammer efficiency.

Up to now, it was necessary to keep track of the serial number and calibration factor of each gage in order to enter this information into the PDA. This step has been eliminated with Pile Dynamics' recent launch of the Smart Gages. Just connect these new accelerometers and strain transducers to the PDA, and the PDA automatically knows to which channel each Smart Gage is connected, the gage number, its calibration and date of last calibration.

The use of the Smart Gages eliminates the need to bring calibration sheets to the job site, saves precious minutes of testing time, and could eliminate the possibility of human error when entering the calibration factors.
