SiteLink®
Technology

The Future of Deep Foundation Testing is already here

Why SiteLink?
SiteLink offers a high tech solution to shrinking budgets and fast track construction. It eliminates scheduling conflicts and the travel of an engineer to the field to conduct the test, minimizing the time until report submittal. The engineer monitors the job remotely, using software that tracks and controls the pile test.

When Dynamic Foundation Testing is done with SiteLink Technology:
A Pile Driving Analyzer® (PDA) with all necessary instrumentation is sent to the field; it’s there when you need it. The construction crew is trained to set up the instrumentation and initiate SiteLink. A highly qualified PDA engineer performs the entire test from any location, in real time, exactly as if present on the job.

What is SiteLink?
SiteLink is technology that enables engineers to conduct Dynamic Foundation Testing from wherever they may be.

Foundation Testing on demand anytime – a phone call away

* SiteLink requires TeamViewer software. Purchased separately from a third party.

*The AASHTO Load and Resistance Factor Design (LRFD) Bridge Design Specifications requires that foundations be designed for a Required Nominal Resistance that has to exceed the Factored Load divided by a Resistance Factor. Resistance Factors vary with the capacity verification method (static or dynamic test, wave equation or dynamic formula). LRFD allows for higher Resistance Factors when the number of pile tests is increased, thus allowing a more economical foundation design. Testing 100% of piles dynamically obtains the same favorable resistance factor as static testing in the AASHTO 2010 code.

Proven
SiteLink® Technology in Sweden

In Sweden, SiteLink Technology has been in use since the year 2000. Today, most Dynamic Foundation Tests performed in Sweden employ the technology. A team of just four engineers is able to monitor thirteen Pile Driving Analyzers® dispersed throughout Sweden.

Pile Driving Monitoring with SiteLink®

During pre-construction test programs, Pile Driving Monitoring with SiteLink speeds up the formulation of a driving criterion. Production piles are started sooner.

During production, piles are driven according to the established criterion. An engineer monitors selected piles with SiteLink technology. If problems develop, the engineer immediately detects them and instructs the crew to stop driving.

iCAP calculates capacity at the time of testing through a signal matching procedure performed during Pile Driving Monitoring. Because it is based on CAPWAP® logic, it is a step beyond capacity determined by the Case Method. With no user interaction, iCAP extracts the soil behavior from dynamic measurements, computes capacity at the time of test, and produces a simulated static load test graph in real time.

Capacity at the time of Testing (Case Method and iCAP®)

Driving Hammer Performance – fundamental for construction control

Driving Stresses – essential for safe pile installation

Pile Integrity

Dynamic Load Testing with SiteLink™
for any type of deep foundation

Results:
Foundation Bearing Capacity
Structural Integrity Assessment
Resistance Distribution

A SiteLink Dynamic Foundation Testing Primer

A PDA with sensors and wireless transmitters is sent to the field. Field personnel attach sensors and transmitters to the pile while it is on the ground, prior to lifting. There are no cables between pile and PDA. No one climbs the leads to attach sensors.

Once the PDA is switched on, it detects the presence of the sensors. As the pile is driven, the sensors collect acceleration and strain signals and transmit them to the PDA. This data is necessary and sufficient to estimate capacity at the time of the test (by Case Method and iCAP), driving stresses, hammer performance, and pile integrity.

Soil resistance often changes following pile installation. For this reason, testing engineers estimate Bearing Capacity from Dynamic Load Tests conducted during re-strike testing. Engineers then evaluate Dynamic Load Test data with the CAPWAP® program. CAPWAP results correlate very well with capacities determined by Static Load Tests.

Dynamic Foundation Testing theory is well documented in the geotechnical engineering literature, and accepted throughout the world. Dynamic Foundation Testing with SiteLink conforms to ASTM D4945 Standard Test Method for High-Strain Dynamic Testing of Piles, and does not compromise the quality or any other aspect of the test.

Engineers testing with SiteLink usually communicate with a project inspector via cellular phone. An on screen message exchange application, part of the SiteLink PDA-W software, is another option. A separate webcam could also provide a live feed during testing.
